

Automate AWS Network Infrastructure Virtual Private Cloud Deployment using Terraform DevOps Tool

TERRAFORM - It is an Infrastructure as a code tool, used primarily by DevOps teams to automate infrastructure tasks.

To understand the concept of Virtual private cloud before writing the terraform code for VPC creation.

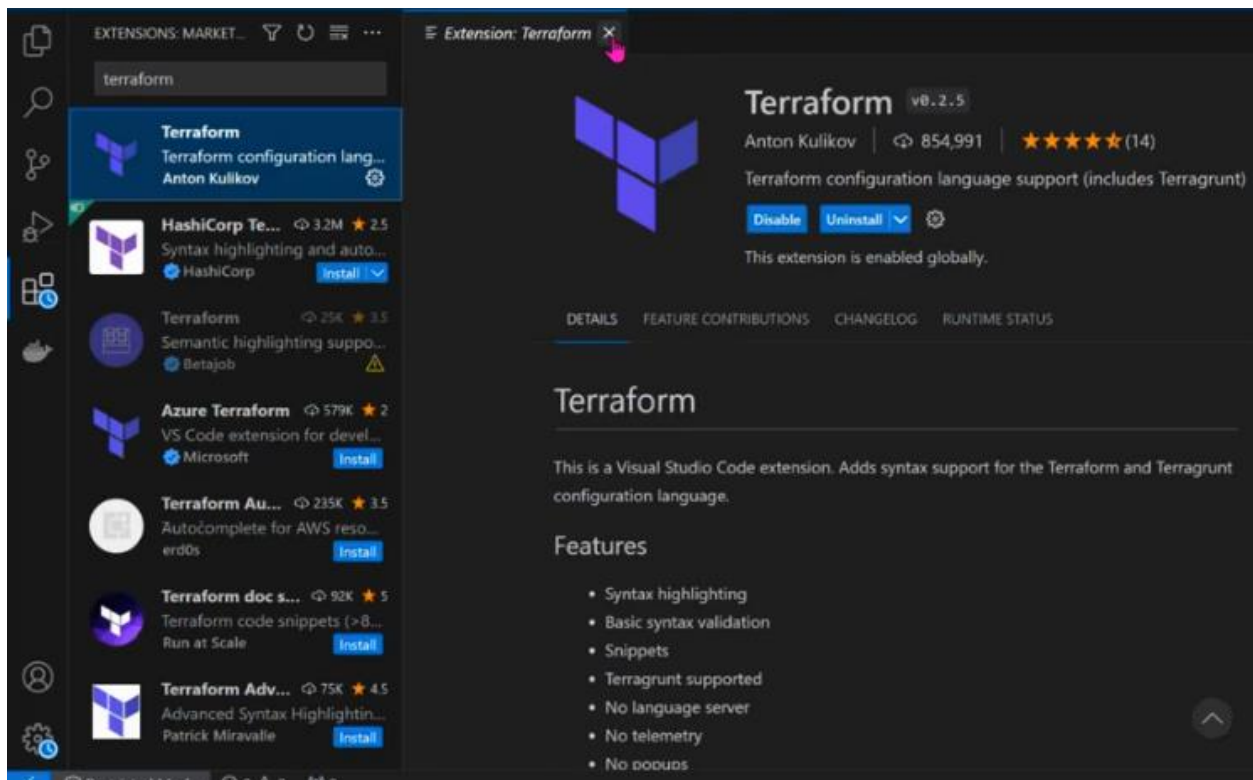

Virtual Private Cloud

Now we have to write the terraform hashicorp programming language to automate AWS Network Infrastructure Virtual Private Cloud Deployment. Refer the terraform hashicorp programming language from terraform registry official website.

We have to write the code in **visual studio code**.

The Main purpose of using Visual studio code: Syntax highlighting, Basic syntax validation, Terragrunt supported.

Before writing the code in visual studio code, we have to complete terraform setup in visual studio code with file name extension as “.tf”

Create the new file with file extension as “.tf”

tf -> Terraform

Now we will start to write the terraform hashicorp programming code to automate AWS Network Infrastructure Virtual Private Cloud Deployment.

Step: 1 -> we will setup terraform cloud provider plugins such as Aws, Azure, GCP cloud etc. Now we will select terraform AWS cloud plugins

```

1 terraform {
2   required_providers {
3     aws = {
4       source = "hashicorp/aws"
5       version = "~> 5.0"
6     }
7   }
8 }
9

```

Step: 2 -> # Configure the AWS Provider with region = "ap-southeast-1"

```

10 # Configure the AWS Provider
11 provider "aws" {
12   region = "ap-southeast-1"
13 }

```

Step: 3 -> # Create VPC with CIDR = "10.0.0.0/16" (10.0.0.0 to 10.0.255.255 = Total -> 65,536 Ip Address)

```

14 resource "aws_vpc" "myvpc" {
15   cidr_block      = "10.0.0.0/16"
16   instance_tenancy = "default"
17
18   tags = {
19     Name = "my-vpc"
20   }
21 }

```

Step: 4 -> To create two subnets. One is for public subnet and another one is private subnets with two different availability zones and CIDR_block.

```

22 resource "aws_subnet" "pubsub" {
23   vpc_id            = aws_vpc.myvpc.id
24   cidr_block        = "10.0.1.0/24"
25   availability_zone  = "ap-southeast-1a"
26
27   tags = {
28     Name = "my-pubsub"
29   }
30 }
31 resource "aws_subnet" "prisub" {
32   vpc_id            = aws_vpc.myvpc.id
33   cidr_block        = "10.0.2.0/24"
34   availability_zone  = "ap-southeast-1b"
35
36   tags = {
37     Name = "my-prisub"
38   }
39 }

```

Step: 5 -> To create internet gateway and attach it to VPC and Public route table.

```

38: resource "aws_internet_gateway" "igw" {
39:   vpc_id = aws_vpc.myvpc.id
40:
41:   tags = {
42:     Name = "myinternet"
43:   }
44: }

```

Step: 6 -> To create two route table. One is for public route table and another one is for private route table.

(a): To create public route table.

```

45: resource "aws_route_table" "pubrt" {
46:   vpc_id = aws_vpc.myvpc.id
47:
48:   route {
49:     cidr_block = "0.0.0.0/0"
50:     gateway_id = aws_internet_gateway.igw.id
51:   }
52:
53:   tags = {
54:     Name = "my-pubrt"
55:   }
56: }

```

(b): We have to create Elastic IP address and Network Address Translation (NAT) before private route table creation. After that we have attach Elastic IP address and Public subnet to NAT.

```

57: resource "aws_eip" "elasticip" {
58:   domain = "vpc"
59: }
60: resource "aws_nat_gateway" "mynat" {
61:   allocation_id = aws_eip.elasticip.id
62:   subnet_id     = aws_subnet.pubsub.id
63:
64:   tags = {
65:     Name = "my-NAT"
66:   }
67: }

```

(c): To create Private Route Table and attach it to NAT to give internet to private network.

```

68: resource "aws_route_table" "prirt" {
69:   vpc_id = aws_vpc.myvpc.id
70:
71:   route {
72:     cidr_block = "0.0.0.0/0"
73:     gateway_id = aws_nat_gateway.mynat.id
74:   }
75:
76:   tags = {
77:     Name = "my-pubrt"
78:   }
79: }

```

Step: 7 -> Route Table association -> To attach public and private subnets to the route table

```

80 resource "aws_route_table_association" "pubass" {
81     subnet_id      = aws_subnet.pubsub.id
82     route_table_id = aws_route_table.pubrt.id
83 }
84 resource "aws_route_table_association" "priass" {
85     subnet_id      = aws_subnet.prisub.id
86     route_table_id = aws_route_table.priort.id
87 }
88 |

```

Step: 8 -> To create Security Group and attach it to VPC.

```

88 resource "aws_security_group" "allowall" {
89     name      = "allow_tls"
90     description = "Allow TLS inbound traffic"
91     vpc_id    = aws_vpc.myvpc.id
92 }

```

```

95 ingress {
96     description = "TLS from VPC"
97     from_port   = 22
98     to_port     = 22
99     protocol    = "tcp"
100    cidr_blocks = ["0.0.0.0/0"]
101 }
102 ingress {
103     description = "TLS from VPC"
104     from_port   = 80
105     to_port     = 80
106     protocol    = "tcp"
107     cidr_blocks = ["0.0.0.0/0"]
108 }
109
110 egress {
111     from_port   = 0
112     to_port     = 0
113     protocol    = "-1"
114     cidr_blocks = ["0.0.0.0/0"]
115 }
116 }

```

```

118 tags = {
119     Name = "security"
120 }
121 }
122

```

Step: 9 -> To create 2 virtual Machines. One is for public and another one is for private.

```

122 resource "aws_instance" "public" {
123     ami                = "ami-0fa7190e664488b99"
124     instance_type      = "t2.micro"
125     subnet_id          = aws_subnet.pubsub.id
126     vpc_security_group_ids = [aws_security_group.allowall.id]
127     key_name            = "ppksing"
128     associate_public_ip_address = true
129 }
130 resource "aws_instance" "private" {
131     ami                = "ami-0fa7190e664488b99"
132     instance_type      = "t2.micro"
133     subnet_id          = aws_subnet.prisub.id
134     vpc_security_group_ids = [aws_security_group.allowall.id]
135     key_name            = "ppksing"
136 }

```

Step: 10 -> To create virtual server (EC2 Instance) in AWS for terraform setup in linux.

To login as Ubuntu linux by using public key

The screenshot shows the AWS Management Console interface. On the left, there's a sidebar with the 'New EC2 Experience' button and links to 'EC2 Dashboard', 'EC2 Global View', and 'Events'. The main area displays the 'Instances (1)' page. At the top, there are buttons for 'Connect', 'Instance state', 'Actions', and 'Launch instances'. Below these is a search bar and a table of instances. The table has columns for Name, Instance ID, Instance state, Instance type, Status check, Alarm status, and Actions. One instance is listed: 'terraform' with ID 'i-02dcf97bdc5b5876', in a 'Running' state, of type 't2.micro', with '2/2 checks passed' status, and 'No alarms'. The 'Actions' column shows a dropdown menu.

```

login as: ubuntu
Authenticating with public key "ppksing"
Welcome to Ubuntu 22.04.2 LTS (GNU/Linux 5.19.0-1025-aws x86_64)

 * Documentation:  https://help.ubuntu.com
 * Management:    https://landscape.canonical.com
 * Support:       https://ubuntu.com/advantage

System information as of Thu Oct  5 05:52:50 UTC 2023

```

```
System load: 0.0          Processes: 94
Usage of /: 20.6% of 7.57GB Users logged in: 0
Memory usage: 23%        IPv4 address for eth0: 172.31.35.78
Swap usage: 0%
```

Expanded Security Maintenance for Applications is not enabled.

0 updates can be applied immediately.

Enable ESM Apps to receive additional future security updates.
See <https://ubuntu.com/esm> or run: `sudo pro status`

The list of available updates is more than a week old.
To check for new updates run: `sudo apt update`

The programs included with the Ubuntu system are free software;
the exact distribution terms for each program are described in the
individual files in `/usr/share/doc/*/copyright`.

Ubuntu comes with ABSOLUTELY NO WARRANTY, to the extent permitted by
applicable law.

To run a command as administrator (user "root"), use "`sudo <command>`".
See "`man sudo_root`" for details.

To convert root user / admin user using command as "sudo -i"

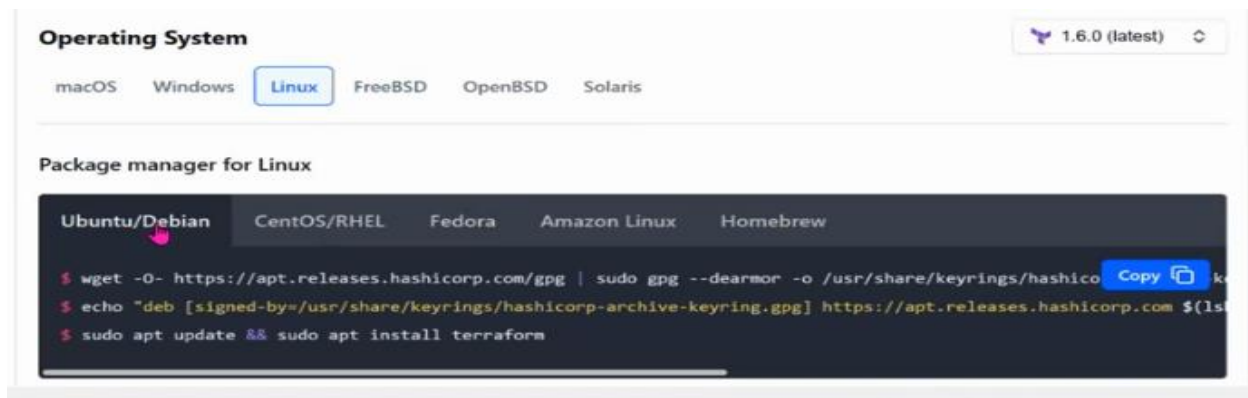

```
ubuntu@ip-172-31-35-78:~$ sudo -i
root@ip-172-31-35-78:~# clear
```

Now we have to install terraform in Ubuntu linux after logged in Ubuntu linux.

Go to Terraform Official website

The screenshot shows a Microsoft Bing search page. The search bar contains the text "terraform download". Below the search bar, there are tabs for SEARCH, CHAT, WORK, IMAGES, VIDEOS, MAPS, NEWS, and SHOPPING. The search results show "About 2,03,000 results". The first result is titled "Install | Terraform | HashiCorp Developer" with a URL "https://www.terraform.io/downloads". The description of the result says: "Install Terraform. Install or update to v1.5.7 (latest version) of Terraform to get started. Operating System. Package manager for macOS. \$ brew tap hashicorp/tap \$ brew install hashicorp/tap/terraform. Binary download for macOS. AMD64. Version: 1.5.7. Download. ARM64. Version: 1.5.7. Download. Release ... See more".

The screenshot shows the Terraform official website. The header has the Terraform logo and navigation links: Terraform, Install, Tutorials, Documentation, Registry, and Try Cloud. There is a search bar with the text "Search" and a keyboard shortcut "⌘/ctrl K". The main content area has a sidebar with links: Terraform Home, Install Terraform, Getting Started, and What is Terraform?. The main content area is titled "Developer / Terraform / Install v1.6.0" and features a large heading "Install Terraform" with a subtext "Install or update to v1.6.0 (latest version) of Terraform to get started." There is also a small icon of the Terraform logo.

Copy the above commands and paste in Ubuntu linux

```
root@ip-172-31-35-78:~#
wget -O- https://apt.releases.hashicorp.com/gpg | sudo gpg --dearmor -o /usr/share/keyrings/hashicorp-archive-keyring.gpg

adminaccess

Create new IAM role [↗](#)

Cancel **Update IAM role**

Now, we have successfully attached IAM role to EC2 instance.

Now, we have to create the file in Ubuntu linux then copy the entire code from visual studio code and paste in **main.tf** file then save and quit.

```
root@ip-172-31-35-78:~# vi main.tf
```

```

egress {
  from_port      = 0
  to_port        = 0
  protocol       = "-1"
  cidr_blocks    = ["0.0.0.0/0"]
}

tags = {
  Name = "security"
}
}

resource "aws_instance" "public" {
  ami                  = "ami-0fa7190e664488b99"
  instance_type        = "t2.micro"
  subnet_id            = aws_subnet.pubsub.id
  vpc_security_group_ids = [aws_security_group.allowall.id]
  key_name              = "ppksing"
  associate_public_ip_address = true
}

resource "aws_instance" "private" {
  ami                  = "ami-0fa7190e664488b99"
  instance_type        = "t2.micro"
  subnet_id            = aws_subnet.prisub.id
  vpc_security_group_ids = [aws_security_group.allowall.id]
  key_name              = "pemsing"
}

:wq!

```

Now we need to apply terraform workflow command one by one in linux.

- **Terraform init** command to initializing provider plugins in backend.

```
root@ip-172-31-35-78:~# terraform init

Initializing the backend...

Initializing provider plugins...
- Finding hashicorp/aws versions matching "~> 5.0"...
- Installing hashicorp/aws v5.19.0...
- Installed hashicorp/aws v5.19.0 (signed by HashiCorp)

Terraform has created a lock file .terraform.lock.hcl to record the provider
selections it made above. Include this file in your version control repository
so that Terraform can guarantee to make the same selections by default when
you run "terraform init" in the future.

Terraform has been successfully initialized!

You may now begin working with Terraform. Try running "terraform plan" to see
any changes that are required for your infrastructure. All Terraform commands
should now work.

If you ever set or change modules or backend configuration for Terraform,
rerun this command to reinitialize your working directory. If you forget, other
commands will detect it and remind you to do so if necessary.
```

- **terraform validate command** is used to verify the correctness of Terraform configuration files

```
terraform validate
```

```
Success! The configuration is valid.
```

- The **terraform plan command** creates a plan consisting of a set of changes that will make your resources match your configuration.

```
terraform plan
```

```
root@ip-172-31-35-78:~# terraform plan

Terraform used the selected providers to generate the following execution plan. Resource actions are indicated
with the following symbols:
+ create

Terraform will perform the following actions:
```

```

+ arn                    = (known after apply)
+ cidr_block              = "10.0.0.0/16"
+ default_network_acl_id  = (known after apply)

```

Plan: 13 to add, 0 to change, 1 to destroy.

- `terraform apply --auto-approve` is the final command for execution

`terraform apply --auto-approve`

Now Virtual Private Cloud has been successfully created on AWS cloud.

Now two virtual machines (Public and private) has been successfully created

Now we have to connect public virtual machine and to check whether the internet is working or not.

public i-027672c9609aa4946 Running t2.micro 2/2 checks passed No alarms +

Instance: i-027672c9609aa4946

[root@ip-10-0-1-155 ~]# clear
```

Now the internet is available and working fine with public network.

After that we have to check whether the internet is working or not in private network.

Now we need to connect private network and click on connect

New EC2 Experience

Instances (1/3) Info

Find instance by attribute or tag (case-sensitive)

Name	Instance ID	Instance state	Instance type	Status check	Alarm status	Av
<input checked="" type="checkbox"/> private	i-0d760fc25361c78a9	Running	t2.micro	2/2 checks passed	No alarms	ap
<input type="checkbox"/> terraform	i-02dcf97bdcc5b5876	Running	t2.micro	2/2 checks passed	No alarms	ap

Connect to instance Info

Connect to your instance i-0d760fc25361c78a9 (private) using any of these options

EC2 Instance Connect
Session Manager
SSH client
EC2 serial console

Instance ID
i-0d760fc25361c78a9 (private)

1. Open an SSH client.
2. Locate your private key file. The key used to launch this instance is pemsing.pem
3. Run this command, if necessary, to ensure your key is not publicly viewable.

```
chmod 400 pemsing.pem
```
4. Connect to your instance using its Private IP:

```
10.0.2.153
```

Example:

```
ssh -i "pemsing.pem" ec2-user@10.0.2.153
```

```
[root@ip-10-0-1-155 ~]# vi pemsing.pem
```

Open the file and paste the private key credential then save and quite then give the permission using the command as “chmod 400 pemsing.pem”

```
[root@ip-10-0-1-155 ~]# vi pemsing.pem
```

```
[root@ip-10-0-1-155 ~]# chmod 400 pemsing.pem
```

```
[root@ip-10-0-1-155 ~]# ssh -i "pemsing.pem" ec2-user@10.0.2.153
The authenticity of host '10.0.2.153 (10.0.2.153)' can't be established.
```

Now the internet is working fine with private network.

```
[ec2-user@ip-10-0-2-153 ~]$ ping google.com
